Sources of drinking water (both tap water and bottled water) include rivers, lakes, streams, ponds, reservoirs, springs, and wells. As water travels over the surface of the land or through the ground, it dissolves naturally-occurring minerals and, in some cases, radioactive material, and can pick up substances resulting from the presence of animals or from human activity. Contaminants that may be present in source water include:

- Microbial contaminants, such as viruses and bacteria, which may come from sewage treatment plants, septic systems, agricultural livestock operations, and wildlife.
- Inorganic contaminants, such as salts and metals, which can be naturally-occurring or result from urban stormwater runoff, industrial or domestic wastewater discharges, oil and gas production, mining, or farming.
- Pesticides and herbicides, which may come from a variety of sources such as agriculture, urban stormwater runoff, and residential uses.
- Organic chemical contaminants, including synthetic and volatile organic chemicals, which are by-products of industrial processes and petroleum production, and can also come from gas stations, urban stormwater runoff, and septic systems.
- Radioactive contaminants, which can be naturally-occurring or be the result of oil and gas production and mining activities.

In order to ensure that tap water is safe to drink, EPA prescribes regulations which limit the amount of certain contaminants in water provided by public water systems. FDA regulations establish limits for contaminants in food. The presence of contaminants does not necessarily indicate that water poses a health risk. More information about contaminants and potential health effects can be obtained by calling the Environmental Protection Agency’s Safe Drinking Water Hotline (800-426-4791).

Substances Naturally Found in Your Water

Drinking water, including bottled water, may reasonably be expected to contain at least small amounts of some contaminants. The presence of contaminants does not necessarily indicate that water poses a health risk. More information about contaminants and potential health effects can be obtained by calling the Environmental Protection Agency’s Safe Drinking Water Hotline (800-426-4791).

Some people may be more vulnerable to contaminants in drinking water than the general population. Immuno-compromised persons such as persons with cancer undergoing chemotherapy, persons who have undergone organ transplants, people with HIV/AIDS or other immune system disorders, some elderly, and infants can be particularly at risk from infections. These people should seek advice about drinking water from their health care providers. EPA/CDC guidelines on appropriate means to lessen the risk of infection by Cryptosporidium and other microbial contaminants are available from the Safe Drinking Water Hotline (800-426-4791).

Definitions

Maximum Contaminant Level (MCL): The highest level of a contaminant that is allowed in drinking water. MCLs are set as close to the MCLGs as feasible using the best available treatment technology.

Maximum Contaminant Level Goal (MCLG): The level of a contaminant in drinking water below which there is no known or expected risk to health. MCLGs allow for a margin of safety.

Action Level (AL): The concentration of a contaminant, which, if exceeded, triggers treatment or other requirements, which a water system must follow.

Notes:

** Sampled in 2011 – none of thirty samples exceeded the action level for lead – Retest 2016

*** Regulated Contaminant monitoring helps EPA to determine where certain contaminants occur and whether it needs to regulate those contaminants. ***MCL for turbidity and TOC is a treatment technique

****EPA considers 50 pCi/L to be the level of concern for beta particles. The MCL for beta particles is 4 mrem/year.

Nephelometric Turbidity Unit (NTU): The measure of turbidity in the water.

ppb: Parts per billion, or micrograms per liter (µg/L)

Treatment Technique (TT): A required process intended to reduce the level of a contaminant in drinking water.

Maximum Residual Disinfection Level (MRDL): Maximum level of disinfectant allowed in drinking water. There is convincing evidence that addition of a disinfectant is necessary for the control of microbial contaminants

Maximum Residual Disinfection Level Goal (MRDLG): The level of a disinfecting water disinfected below which there is no known or expected risk to health. MRDLG’s do not reflect the benefits of the use of disinfectants to control microbial contamination.
**Cryptosporidium**

Cryptosporidium is a microbial pathogen found in surface water throughout the U.S. Although filtration removes Cryptosporidium, the most commonly-used filtration methods cannot guarantee 100 percent removal. ARWA’s monitoring indicates the presence of these organisms in the source water. Current test methods do not allow us to determine if these organisms are dead or if they are capable of causing disease. Additional information is available from the Safe Drinking Water Hotline (800-426-4791).

**Source Water Assessment**

The Virginia Dept. of Health conducted a source water assessment of ARWA’s system during 2002. Lake Chesdin (Appomattox River) was determined to be of high susceptibility to contamination using criteria developed by the State in its EPA-approved Source Water Assessment Program. The assessment report consists of maps showing the source water assessment area, an inventory of known land use activities of concern, and documentation of any known contamination within the last five years from date of assessment. The report is available by contacting Dr. Robert C. Wichser, P.E., ARWA at (804)-590-1145.

**Operation Changes**

During hot weather, chlorine tends to degrade in the storage tanks due to the high temperatures. This reduction in chlorine levels can lead to bacteriological problems in the system.

System operation is designed to insure the proper level of residual chlorine in the system. Tank levels are fluctuated at least 20% daily. The system flush program is scheduled to occur during the hottest period, and last for a six-week period. Dead end areas of the system are flushed on a weekly basis during warm weather.

**Lead Levels**

Infants and young children are typically more vulnerable to lead in drinking water than the general population. It is possible that lead levels at your home may be higher than at other homes in the community as a result of materials used in your home’s plumbing. If you are concerned about elevated lead levels in your home’s water, you may wish to have your water tested and flush your tap for 30 seconds to 2 minutes before using tap water. Additional information is available from the Safe Drinking Water Hotline (800-426-4791).

**Citizen Input Welcome**

If you have questions or comments of any kind about this report or your drinking water, please do not hesitate to contact the Public Utilities Office at (804) 733-2407.
